# AEM10941 Evaluation Kit with PowerFilm Flexible PV Cell and CAP-XX Supercapacitor User Guide

# Description

The **AEM10941** is an ambient energy manager that extracts power from photovoltaic harvesters with high efficiency from 0.5V to 5V input voltage and simultaneously store energy in a rechargeable element and supply your system with two independent regulated voltages able to deliver up to 80 mA from 1.8 V to 4.5 V. It is able to coldstart with an input power as low as 3  $\mu$ W at 380 mV.

The **AEM10941** evaluation board with flexible solar cell allows users to test the e-peas IC and the **PowerFilm** PV cell and analyse its performances in a laboratory-like setting. It allows easy connections to the **CAP-XX** supercapacitor and the low voltage and high-voltage loads. It also provides all the configuration access to set the device in any one of the modes described in the datasheet. The control and status signals are available on standard pin headers, allowing users to configure it for any usage scenario and evaluate the relevant performances.

The **AEM10941** evaluation board with **PowerFilm** flexible solar cell and **CAP-XX** supercapacitor is a plug and play, intuitive and efficient tool for making the appropriate decisions (component selection, operating modes, etc) for the design of a highly efficient subsystem in your target application.

# **Applications**

PV cell harvestingHome automationIndustrial monitoringE-health monitoringGeolocationWireless sensor nodes

## **Device Information**

| Part Number        | Dimensions             |
|--------------------|------------------------|
| 2EAEM10941C0011    | 49 mm x 58 mm          |
| LL200-2.4-37       | 54 mm x 36.5 mm        |
| MPT2.4-21          | 54 mm x 20.9 mm        |
| DMT3N4R2U224M3DTA0 | 21 mm x 14 mm x 2.2 mm |
| GY12R705012S504R   | 5 mm x 12 mm           |
| GA209F             | 20 mm x 18 mm x 2.1 mm |

## Features

**Two-way screw terminals** 

- Source of energy (PV cell)
- Primary battery
- High-voltage load
- Low-voltage load

#### Three-way screw terminals

• Custom mode configuration

#### **3-pin headers**

- Energy storage element threshold configuration (CFG[2:0])
- Low drop-out regulators (LDOs) enabling
- Dual-cell supercapacitor configuration

One 2-pin header

• Primary battery configuration

**Provision for five resistors** 

- Custom mode configuration
- Cold-start configuration
- Primary battery configuration

#### PowerFilm PV Modules

- Sample modules produces up to 1 mW indoors or 68 mW outdoors when two modules are connected in parallel (do not series connect, or maximum voltage will be exceeded)
- Thin-film solar modules on a flexible plastic substrate
- Custom size, power and configurations available

#### **CAP-XX** supercapacitor

- Model GA209F Best for faster, efficient charging (low ESR) Thin prismatic, dual cells 5V, 90mF datasheet
- Model DMT3N4R2U224M3DTA0 Thin prismatic, dual cells, 4.2V, 220mF datasheet
- Model GY12R705012S504R Cylindrical, lowest cost, 500mF, 2.7V datasheet

**PowerFilm**. CAP-XX SUPERCAPACITOR

# 1.1. Signals Description

| NAME            | FUNCTION  | CONNECTION  |                                       |  |  |
|-----------------|---|---|---------------------------------------|--|--|
|                 |   | If used   | If not used                           |  |  |
| Power signals   |   |   |                                       |  |  |
| SRC             | Connection to the harvested energy source (PV cell).  | Connect the source element.                                     | Leave floating.                       |  |  |
| BATT            | Connection to the energy storage element.   | Connect the storage<br>element in addition to<br>CSTO (150 µF). | Do not remove CBATT                   |  |  |
| BAL             | Connection to mid-point of a dual-cell supercapacitor   | Leave R30 empty.  | Use R30 to connect "BAL"<br>to "GND"  |  |  |
| PRIM            | Connection to the primary battery   | Connect primary battery and remove R26                          | Use R26 to connect<br>"PRIM" to "GND" |  |  |
| LVOUT           | Output of the low-voltage LDO regulator.  | Connect a load  |                                       |  |  |
| HVOUT           | Output of the high-voltage LDO regulator.   | Connect a load  |                                       |  |  |
| Configuration s | ignals  |   |                                       |  |  |
| CFG[2:0]        | Configuration of the threshold voltages for the energy storage element.   | Connect jumpers (see<br>Table 2)                                | Cannot be left floating.              |  |  |
| SELMPP[1:0]     | Configuration of the MPP ratio.   | Connect with 0 $\Omega$ resistor (see Table 4).                 | Cannot be left floating.              |  |  |
| FB_PRIM         | Configuration of the primary battery.   | Use resistors R7-R8 and jumpers (see Section 2.4.2).            | Leave R8 empty.                       |  |  |
| FB_HV           | Configuration of the high-voltage LDO in the custom mode  | Use resistor R5-R6<br>(see Section 2.4.1).                      | Leave R5-R6 empty.                    |  |  |
| Control signals |   |   |                                       |  |  |
| ENHV            | Enabling pin for the high-voltage LDO.  | Connect jumper<br>(see Table 3).                                | Cannot be left floating.              |  |  |
| ENLV            | Enabling pin for the low-voltage LDO.   | Connect jumper<br>(see Table 3).                                | Cannot be left floating.              |  |  |
| Status signals  |   |   |                                       |  |  |
| STATUS[2]       | Logic output. Asserted when the AEM performs the MPP evaluation.  | May be connected to a monitoring circuit                        | Can be left floating                  |  |  |
| STATUS[1]       | Logic output. Asserted if the battery voltage falls<br>under Vovdis or if the AEM is taking energy from<br>the primary battery. | May be connected to a monitoring circuit                        | Can be left floating                  |  |  |
| STATUS[0]       | Logic output. Asserted when the LDOs can be enabled.  | May be connected to a monitoring circuit                        | Can be left floating                  |  |  |

Table 1: Pin description

# 2. General Considerations

## 2.1. Safety Information

Always connect the elements in the following order:

- 1. Reset the board see Section 2.2 "Reseting the board".
- 2. Completely configure the PCB (resistors);

MPP configuration (SELMPP[0], SELMPP[1] - see Table 4, Battery and LDOs configuration (CFG[2:0] and, if needed, R1-R2-R3-R4-R5-R6) - see Table 2, Primary battery configuration (R7-R8) - see Section 2.4.2, LDOs enabling (ENHV and ENLV) -Section 2.3, Balun circuit connection (BAL) - see Section 2.4.4,

- 3. Connect the storage elements on BATT and optionally the primary battery on PRIM.
- 4. Connect the high and/or low voltage loads on HVOUT/LVOUT (optional).
- 5. Connect the source on SRC.

To avoid damage to the board, users are urged to follow this procedure. To store the board, disconnect SRC and the load. Disconnect the storage element (if possible) and reset the board.

## 2.2. Reseting the board

#### How to reset the AEM10941 evaluation board:

To reset the board, simply disconnect the source and the optional primary battery and press the "RESET" button.

# 2.3. Basic Configurations

| Cor    | Configuration pins |        | Storage element threshold voltages |                                 | LDOs outp          | ut voltages     | Typical use     |                                  |
|--------|--------------------|--------|------------------------------------|---------------------------------|--------------------|-----------------|-----------------|----------------------------------|
| CFG[2] | CFG[1]             | CFG[0] | V <sub>OVCH</sub>                  | V <sub>CHRDY</sub>              | V <sub>OVDIS</sub> | V <sub>HV</sub> | V <sub>LV</sub> |                                  |

| L         | Н         | 75%      |
| Н         | L         | 85%      |
| Н         | Н         | 90%      |

Table 4: Usage of SELMPP[1:0]

## 2.4. Advanced Configurations

A complete description of the system constraints and configurations is available in Section 8 "System configuration" of the AEM10941 datasheet.

A reminder on how to compute the configuration resistors value is provided below. Calculation can be made with the help of the spreadsheet found at the e-peas website.

## 2.4.1. Custom mode

In addition to the pre-defined protection levels, the custom mode allows users to define their own levels via resistors R1 to R4 and to tune the output of the high voltage LDO via resistors R5-R6. The custom mode is accessible via the configuration 000 and the removal of resistor R21.

By defining RT = R1 + R2 + R3 + R4 ( $1M\Omega \le RT \le 100 M\Omega$ ):

 $\begin{array}{l} \text{R1} = \text{RT} \left( 1\text{V} \ / \ \text{V}_{\text{OVCH}} \right) \\ \text{R2} = \text{RT} \left( 1\text{V} \ / \ \text{V}_{\text{CHRDY}} - 1\text{V} \ / \ \text{V}_{\text{OVCH}} \right) \\ \text{R3} = \text{RT} \left( 1\text{V} \ / \ \text{V}_{\text{OVDIS}} - 1\text{V} \ / \ \text{V}_{\text{CHRDY}} \right) \\ \text{R4} = \text{RT} \left( 1 - 1\text{V} \ / \ \text{V}_{\text{OVDIS}} \right) \\ \text{By defining RV} = \text{R5} + \text{R6} \left( 1\text{M}\Omega \le \text{RV} \le 40\text{M}\Omega \right) : \end{array}$ 

 $R5 = RV (1V / V_{HV})$ 

 $R6 = RV (1 - 1V / V_{HV})$ 

Make sure the protection levels satisfy the following conditions:

$$\begin{split} & \mathsf{V}_{\mathsf{CHRDY}} + 0.05 \; \mathsf{V} \leq \mathsf{V}_{\mathsf{OVCH}} \leq 4.5 \; \mathsf{V} \\ & \mathsf{V}_{\mathsf{OVDIS}} + 0.05 \; \mathsf{V} \leq \mathsf{V}_{\mathsf{CHRDY}} \leq \mathsf{V}_{\mathsf{OVCH}} - 0.05 \; \mathsf{V} \\ & 2.2 \; \mathsf{V} \leq \mathsf{V}_{\mathsf{OVDIS}} \\ & \mathsf{V}_{\mathsf{HV}} \leq \mathsf{V}_{\mathsf{OVDIS}} - 0.3 \mathsf{V} \end{split}$$

If unused, leave the resistor footprints (R1, R4, R5 and R6) empty.

## 2.4.2. Primary battery configuration

If the primary storage is used, its battery protection levels have to be defined. To do so, use resistors R7 - R8. Please add a 1  $\mu$ F capacitor in parallel with the primary battery too. This capacitor must remain connected to the circuit at all time.

By defining RP = R7 + R8 (100 k $\Omega \le RP \le 10M\Omega$ ):

R7 = V<sub>PRIM,MIN</sub> / 4 \* RP \* 1 / 2.2 V R8 = RP - R7

If unused, leave resistor R29 in place.

#### 2.4.3. Cold-start configuration

The cold-start voltage Vcs (i.e. the voltage needed at startup to turn on the AEM10941) is by default at its minimum value of 380mV. This voltage can be increased by the use of resistors R9-R10.

By defining RC = R9 + R10 ( $100k\Omega \le RC \le 10M\Omega$ ):

R9 = 0.38V \* RC / Vcs R10 = RC - R9 If unused, do not mount resistors R9-R10.

#### 2.4.4. Balun circuit configuration

When using a dual-cell supercapacitor (that does not already include a balancing circuit), enable the balun circuit configuration to ensure equal voltage on both cells. To do so:

Connect the node between the two supercapacitor cells to BAL (BATT connector) Remove resistor R30

If unused, leave resistor R30 in place.

**USER GUIDE** 

# 3. PowerFilm PV cells

PowerFilm designs and manufactures custom solar cells, modules, panels and power solutions for energy harvesting and portable power applications using proprietary thin-film silicon technology. In business for over 30 years, we continue to provide a wide range of rugged, high-performance

solutions across IoT, transportation, military, and consumer markets.

Our proprietary PV material is inherently sensitive to collecting low intensity light, making it ideal for low power indoor/outdoor IoT and energy harvesting applications where

light conditions are always changing. Indoor Light Series panels have excellent performance under artificial lighting, whether it is a dim warehouse (200 lux) or a bright retail store (1000 lux). Classic Application Series panels are optimized for collecting outdoor light directly from the sun or indirectly in shaded areas.

Starting with polyimide plastic, our panels are manufactured using high throughput, roll-to-roll processes. With only simple adjustments, we can print solar cells and modules in many different custom sizes and configurations, helping our customers solve IoT power problems in innovative ways.

| Cell name    | Illuminance | Voc(V) | lsc(μA) | Vmp(V) | Impp (µA) | Pmp (μW) | Voc/Vop Ratio |
|--------------|-------------|--------|---------|--------|-----------|----------|---------------|
| LL200-2.4-37 | 200 lux     | 2.2    | 60      | 1.6    | 43        | 69       |               |
|              | 1000 lux    | 2.9    | 200     | 2.1    | 214       | 449      | 73%           |

|              | 1 sun       | 3.3    | 18300   | 2.4    | 14200     | 38340    |               |

 Table 5: PowerFilm PV Modules. Vop, Iop, and Pop represent guaranteed minimum performance. Other listed values are average or typical

 behavior. Indoor Light Series panels are tested for performance under a cool white LED spectrum.

## 4. CAP-XX supercapacitors

CAP-XX is a world leader in the design and manufacture of thin, flat supercapacitors and energy management systems used in portable and small-scale electronic devices.

The unique feature of CAP-XX supercapacitors is their very high power density and high energy storage capacity in a space-efficient prismatic package. These attributes are essential in power-hungry consumer and industrial electronics, and deliver similar benefits in automotive and other transportation applications.

| Voltage (V) | Capacitance (mF) | ESR (mΩ) | Dimensions (mm) | Height (mm) | Part name          |

Table 7: Footprint description

This footprint is available on the inferior face of the PCB. The red colour represents the positive voltage, the blue is the ground and the black is to be connected to the balancing pin. Those three potentials are available on the screw terminal on the top side.

## 5. Functional Tests

This section presents a few simple tests that allow the user to understand the functional behaviour of the AEM10941. To avoid damaging the board, follow the procedure found in Section 2.1 "Safety Information". If a test has to be restarted make sure to properly reset the system to obtain reproducible results.

The following functional tests were made using the following setup:

Configuration: SELMPP[1:0] = LL, CFG[2:0] = HLL, ENHV = H, ENLV = H

Storage element: Capacitor (4.7 mF + CBATT)

Load: 10k $\Omega$  on HVOUT, LVOUT floating

SRC: current source (1mA or 100µA) with voltage compliance (4V)

Feel free to adapt the setup to match your system as long as you respect the input and cold-start constraints (see Section 1 "introduction" of AEM10941 datasheet).

## 5.1. Start-up

The following example allows users to observe the behaviour of the AEM10941 in the wake-up mode.

#### Setup

Place the probes on the nodes to be observed.

Referring to Figure 1, follow steps 1 to 5 explained in Section 2.1 "Safety Information".

#### **Observations and measurements**

- BATT: Voltage rises as the power provided by the source is transferred to the storage element (see Figure 2).
- SRC: Regulated at Vmpp, which is a voltage equal to the open-circuit voltage (Voc) times the MPP ratio defined in Table 4. Vsrc equals Voc during MPP evaluation (see Figure 3). Note that Vsrc must be higher than 380 mV to coldstart.
- HVOUT/LVOUT: regulated when voltage on BATT first rises above Vchrdy (see Figure 2).
- STATUS[0]: Asserted when the LDOs are ready to be enabled (see Figure 2).
- STATUS[2]: Asserted each time the AEM10941 performs a MPP evaluation (See Figure 3).

Figure 2: STATUS[0] and HVOUT evolution with BATT

Figure 3: SRC and STATUS[2] while energy is extracted from SRC (BATT under V<sub>OVCH</sub>)

## 5.2. Shutdown

This test allows users to observe the behaviour of the AEM10941 when the system is running out of energy.

#### Setup

Place the probes on the nodes to be observed.

- Referring to Figure 1, follow steps 1 to 5 explained in Section 2.1 "Safety Information". Configure the board in the desired state and start the system (see Section 3.1). Do not use a primary battery.
- Let the system reach a steady state (i.e. voltage on BATT between V<sub>CHRDY</sub> and V<sub>OVCH</sub> and STATUS[0] asserted).
- Remove the PowerFilm PV cell and let the system discharge through quiescent current and HVOUT/LVOUT load(s).

#### **Observations and measurements**

- BATT: Voltage decreases as the system consumes the power accumulated in the storage element. The voltage remains stable after crossing V<sub>OVDIS</sub> (see Figure 4).
- STATUS[0]: De-asserted when the LDOs are no longer available as the storage element is running out of energy. This happens 600 ms after STATUS[1] assertion (see Figure 4).
- STATUS[1]: Asserted for 600ms when the storage element voltage (BATT) falls below V<sub>OVDIS</sub> (see Figure 4).

Figure 4: LDOs disabled around 600 ms after BATT reaches Vovdis

## 5.3. Switching on primary battery

This example allows users to observe switching from the main storage element to the primary battery when the system is running out of energy.

#### Setup

Place the probes on the nodes to be observed.

- Referring to Figure 1, follow steps 1 to 5 explained in Section 2.1 "Safety Information". Configure the board in the desired state and start the system (see Section 3.1). Connect a primary battery (example: 3.1V coin cell with protection level at 2.4V, R7 =  $68k\Omega$  and R8 =  $180k\Omega$ ).
- Let the system reach a steady state (i.e. voltage on BATT between  $V_{CHRDY}$  and  $V_{OVDIS}$  and STATUS[0] asserted).
- Remove the PV cell and let the system discharge through quiescent current and HVOUT/LVOUT load(s).

#### **Observations and measurements**

- BATT: Voltage decreases as the system consumes the power accumulated in the storage element. The voltage reaches V<sub>OVDIS</sub> and than rises again to BATT as it is recharged from the primary battery (see Figure 5).
- STATUS[0]: Never de-asserted as the LDOs are still functional (see Figure 5).
- HVOUT: Stable and not affected by switching on the primary battery (see Figure 5).

Figure 5: Switching from SRC to the primary battery

## 5.4. Cold start

The following test allows the user to observe the minimum voltage required to coldstart the AEM10941. To prevent leakage current induced by the probe the user should avoid probing any unnecessary node. Make sure to properly reset the board to observe the cold-start behaviour.

#### Setup

Place the probes on the nodes to be observed.

Referring Figure 1, follow steps 1 and 2 explained in Section 2.1. Configure the board in the desired state. Connect to FB\_COLD. Do not plug any storage element in addition to CBATT.

SRC: Connect your source element.

#### **Observations and measurements**

- SRC: Equal to the cold-start voltage during the coldstart phase. Regulated at the selected MPPT percentage of  $V_{OC}$  when cold start is over. (See Figure 6). Be careful that the cold-start phase time will shorten with the input power. Limit it to ease the observation.
- BATT: Starts to charge when the cold-start phase is over (see Figure 6).

Figure 6: AEM10941 behaviour during cold start

# 5.5. Dual-cell supercapacitor balancing circuit

The following test allows the user to observe the balancing circuit behaviour that balances the voltage on both side of the BAL pin.

#### Setup

- Following steps 1 and 2 explained in section 2.1 and referring to Figure 1, configure the board in the desired state. Disconnect the resistor R30.
- BATT: Plug capacitor C1 between the positive (+) pin and the bal pin, and a capacitor C2 between the BAL pin and the negative (-) pin.
  - C1 & C2 > 1 mF
  - (C2 \* V<sub>CHRDY</sub>) / C1 ≥ 0.9V

SRC: Plug your source element to power up the system. **Observations and measurements** 

BAL: equal to half the voltage on BATT.

#### Warning regarding measurements:

Any item connected to the PCB (load, probe, storage device, etc.) involves a leakage current. This can negatively impact the measurements. Whenever possible, disconnect unused items to limit this effect.

# 6. Performance Tests

This section presents the tests to reproduce the performance graphs found in the AEM10941 datasheet and to understand the functionalities of the AEM10941. to be able to reproduce those tests, you will need the following:

1 voltage source

2 source measure units (SMUs)

1oscilloscope

To avoid damaging the board, follow the procedure in Section 2.1 "Safety information". If a test has to be restarted, make sure to properly reset the system to obtain reproducible results.

## 6.1. LDOs

The following example instructs users on how to measure the output voltage stability of the LDOs (Figure 16 and Figure 17 of the AEM10941 datasheet).

#### Setup

- Referring to Figure 1, follow steps 1 and 2 explained in the section 2.1. Configure the board in the desired state and plug your storage element(s)
- VBOOST: connect SMU1. configure it to source voltage with a current compliance of 200 mA.
- HVOUT / LVOUT: connect SMU2 to the LDO you want to measure. Configure it to sink current with a voltage compliance of 5V for HVOUT or 2.5V for LVOUT.

#### Manipulations

Impose a voltage between  $\rm V_{\rm OVCH}$  and 5V on SMU 1 to force the AEM to start.

Sweep voltage on SMU1 from V<sub>OVDIS</sub> + 50 mV to 4.5 V Repeat with different current levels on SMU2 (from 10 $\mu$ A

# to 80mA for HVOUT and from 10 $\mu A$ to 20mA for LVOUT). Measurements

HVOUT/LVOUT: Measure the voltage.

Figure 7: HVOUT at 2.5V

## 6.2. BOOST efficiency

This test allows users to reproduce the efficiency graphs of the boost converter (Figure 14 of the AEM10941 datasheet).

#### Setup

- Following steps 1 and 2 explained in the section 2.1 and referring to Figure 1, configure the board in the desired state.
- VBUCK: Connect a 2.3 V voltage source to prevent VBUCK to sink from VBOOST.
- SRC (: Connect SMU1. Configure it to source current with a voltage compliance of 0 V.
- VBOOST: Connect SMU2. Configure it to source voltage with a current compliance of 200 mV

STATUS[2] Connect to one of the SMU to detect falling edge.

#### Manipulations

- Impose a voltage between  $V_{OVCH}$  and 5V on SMU 2 to force the AEM to start. When done, impose a voltage between  $V_{OVDIS}$  + 50mV and  $V_{OVCH}$ .
- Sweep voltage compliance on SMU1 from  $V_{\mbox{OVDIS}}$  + 50 mV to 4.5 V
- Repeat with different current levels on SMU1 (from 100 $\mu$ A to 100mA) and with different voltage levels on SMU2 (from V<sub>OVDIS</sub> + 50 mV to V<sub>OVCH</sub>).

#### Measurements

STATUS[2]: Dot not make any measurements while high (boost converter is not active during MPP calculation).SRC: Measure the current and the voltage.

VBOOST: Measure the current and the voltage. Repeat the measurement a copious number of times to be sure to capture the current peaks. Figure 8 has been obtained by averaging over 100 measurements configured with a 100 ms integration time.

Deduce input and output power (P = U x I) and efficiency ( $\eta$  = Pout/Pin).

Figure 8: Boost efficiency for ISRC = 1mA

## 6.3. Custom mode configuration

This test allows users to measure the custom protection levels of the storage element set by resistors R1 to R6.

#### Setup

Referring to Figure 1, follow steps 1 and 2 explained in Section 2.1. Connect CFG[2:0] = LLL to select custom mode, remove R2, R3 and R25 and choose R1 to R6 to configure the battery protection levels and HVOUT output voltage.

Place the probes on the nodes to be observed.

SRC: connect your source element to power up the system. Manipulations

Remove the source element after the voltage on BATT has reached steady state (between  $V_{CHRDY}$  and  $V_{OVCH}$ ).

#### Measurements

Measure the following nodes to ensure the correct behaviour of the AEM10941 with respect to the custom configuration:

STATUS[0]: Asserted when the LDOs can be enabled (i.e. when BATT first rises above V<sub>CHRDY</sub>).

STATUS[1]: Asserted when BATT falls below  $V_{OVDIS}$ .

BATT: Rise up and oscillate around V<sub>OVCH</sub> as long as the source element has not been removed.

HVOUT: Equal to the value set by R5-R6

# 7. PV cell characterization

Figure 9: PV cell first order model

A photovoltaic cell can be modelled at first approximation by a light-controlled current source in parallel with a diode as illustrated in Figure 9. This allows two characteristics of a PV cell to be modelled: open circuit voltage (Voc) and short circuit current (Isc)

The open-circuit voltage corresponds to the forward voltage of the diode at no load while the short-circuit current is the current delivered by the current source (i.e. when shorting the + and - terminals).

Figure 11: Typical power-V curve of a PV cell for high and low illumination level

As can be seen in Figure 11, the power significantly decreases with the voltage beyond the optimum Vmpp. It is then recommended to configure the Vmpp/Voc ratio to be slightly lower than the theoretical optimum and therefore avoid a significant drop of performance.

Figure 10: Typical I-V curve of a PV cell for high and low illumination level

Typical current vs voltage graph of a PV cell for different illumination levels can be observed in Figure 10. Knowing that P = I \* V, the associated power vs voltage curves can be drawn as shown in Figure 11. For a given technology, the maximum extracted power is achieved at a voltage corresponding to a given ratio of the open-circuit voltage (between 70% and 90%). This ratio is, in first approximation, independent of the illumination level: as can be seen in Figure 11, Vmpp / Voc  $\approx$  Vmpp / Voc.

As presented in Table 4, the MPP configuration of the AEM10941 allows you to select the voltage ratio that optimizes the power extraction according to the
